# Morbidity and Mortality

Weekly Report

U. S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

PUBLIC HEALTH SERVICE

Prepared by the

COMMUNICABLE DISEASE CENTER

634-5131

For release August 7, 1964

ATLANTA, GEORGIA 30333

Vol. 13, No. 31

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE CONTROL OF THE AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED AUGUST 1, 1964

TULAREMIA

A total of 9 cases of tularemia was reported for the week ended August 1. This brings to 197 the cumulative total for 1964. For the comparable period of 1963, 170 cases were reported. Weekly reporting of cases began in 1962; these cases and the annual totals for the past 5 years are shown in the accompanying table.

The 4 States in the West South Central region account for 66 cases (34 percent of the national total). Arkansas has reported 37 of these cases; this total is the highest for any State. Missouri has the second highest State total, 22 cases.

To date, cases have been reported in all but the New England, Middle Atlantic and Pacific regions.

During this time of year, the majority of the cases occur following tick bites; in the fall and winter, most cases result from handling infected rabbits.

<sup>\*</sup> Includes revised and delayed reports.

### POST-INFECTIOUS ENCEPHALITIS - JUNE

A total of 117 cases of post-infectious encephalitis was reported for the 4-week period ended June 27 (see table above). This brings to 528 the cumulative total of post-infectious encephalitis cases reported for the first half of 1964.

The totals for the previous 5 months, including delayed and revised reports, are shown in the table below. (For earlier reports, see MMWR, Vol. 13, pp 46, 102, 143, 177 and 219.) Mumps and measles continued to account for a large majority of the cases reported, with mumps the chief inciting cause in 54 percent of the cases reported in June.

A comparison of the cases attributed to mumps, measles and other causes is presented by month in the table below.

There were 12 cases of post-chickenpox encephalitis reported; 6 were from California. Chickenpox accounts for 8 percent of the 1964 cumulative total. The monthly incidence in 1964 follows:

January	February	March	April	May	June
1	3	6	15	5	12

The 12 cases of post-rubella encephalitis reported during June are just one less than the total number reported for the first 5 months of 1964. Thus far, rubella accounts for 5 percent of the cumulative total. A table of rubella cases reported by month in 1964 follows:

January	February	Morch	April	May	June
0	2	3	5	3	12

Four cases were reported from Illinois and 3 from Arkansas; these represent the first cases reported from the East North Central and West South Central States this year.

### MALARIA - Illinois

Plasmodium falciparum malaria was diagnosed in a 52-year-old Chicago microbiologist, who acquired the disease while travelling in Africa during January and February 1963. The patient arrived in Uganda January 19, and began prophylactic atabrine on an irregular schedule on January 22.

For the next 4 weeks, he camped and travelled through Uganda, Kenya, Tanganyika, Northern and Southern Rhodesia, Zanzibar, and the Union of South Africa. He returned to the United States via Iran, Israel, Jordan, Lebanon, Italy, and Greece, arriving in New York City February 18. He was asymptomatic throughout this period.

He resumed work on return to the United States, but 3 days later, February 21, he noted a severe headache, nausea and fever on awakening in the morning. Later, he vomited and experienced epigastric and right upper abdominal quadrant pain. The initial clinical impression was "flu." Because of the persistence of these symptoms and a fever which spiked to 103° for 3 successive days, he was hospitalized February 25. Malaria was diagnosed on peripheral blood smear.

During hospitalization, the patient's course was complicated by hemolytic anemia, severe bone marrow depression, and acute renal shutdown, requiring hemodialysis. The patient was treated with chloroquine, and he has recovered without known sequellae.

P. falciparum was diagnosed on blood smears submitted to the National Malaria Slide Repository, Communicable Disease Center.

(Reported by Norman J. Rose, M.D., Chief, Bureau of Epidemiology, Illinois Department of Public Health, and Harry B. Harding, M.D., Clinical Microbiologist, Evanston.)

Editor's Note: This case of malaria is a sharp reminder of the necessity of starting proper prophylactic antimalarials before travelling in a malarious region, and rigidly continuing such therapy while in danger of such exposure.

### SALMONELLOSIS - California

From 5½ to 36 hours after sharing a common meal, June 23, all 10 individuals experienced symptoms of gastroenteritis in an outbreak of salmonellosis. The patients were aged 2 to 65 and involved members of 3 families. They experienced vomiting, abdominal cramps, diarrhea and slight fever for an average of 4 days. All recovered after hospitalization. The incubation period and severity of illness correlated with the amount of the suspect food eaten. The menu consisted of fried chicken, gravy, canned creamed corn, green salad with mayonnaise, mashed potatoes, and cake. All guests ate the chicken and gravy; several did not eat the other items.

The family raised its own chickens. Two weeks earlier, the family killed and dressed 8 chickens, which were placed in a freezer until the day of the meal. They were removed during the morning of June 23 and allowed to thaw. At 3 o'clock, they were fried; at 4:30 p.m., the gravy was made in the same frying pan in which the chicken had been prepared. Some gravy was added to the creamed corn. The chicken and gravy were warmed on the top of the stove until 7:30 p.m. when the meal was served.

Salmonella newport was isolated from 8 of 9 stool samples collected from the patients; the negative culture was from the victim with the mildest symptoms. The same organism was isolated from a left-over piece of chicken and from the gravy. A few colonies of S. newport were recovered from the creamed corn. The organism was not recovered from other food items remaining from the meal. Attempts to trace the source of contamination were not reported.

(Reported by Richard I. Church, R.S., Supervising Sanitarian, and Philip A. Bearg, M.D., Assistant District Health Officer, San Joaquin Health District, and Philip K. Condit, M.D., Chief, Bureau of Communicable Diseases, California Department of Health.)

### CADMIUM POISONING - California

From 30-45 minutes after drinking pink lemonade, 23 school children, aged 5 to 9, experienced abdominal cramps and vomiting in an outbreak due to cadmium contamination. All recovered within 48 hours. The severity of symptoms correlated with the amount of lemonade consumed. Nine other children, who only tasted or consumed small amounts of the lemonade, did not become ill. Each child brought a lunch from home; the lemonade was the only food common to all 32.

The lemonade was prepared by adding the proper amount of city water and ice cubes to 3 cans of a commercially prepared concentrate. The mixture was placed in a 3-gallon cadmium plated war surplus container for the 3-1/2 hour interval between preparation and serving.

Laboratory analysis of a sample of the remaining lemonade revealed 21 parts per million of cadmium, a dosage considered sufficient to cause the symptoms in the children.

(Reported by W. B. Walshe, Chief, Division of Sanitation, and J. B. Askew, M.D., Director of Public Health, San Diego County Department of Public Health, and Dr. Philip K. Condit, Chief, Bureau of Communicable Diseases, California State Department of Health.)

Editor's Note: An unrelated outbreak of cadmium poisoning was reported in MMWR, Vol. 13, p. 258.

\*Estimate - based on average percent of divisional total. Totals for previous weeks include reported corrections.

### INFANT DEATHS IN 108 CITIES

The weekly average number of infant deaths in 108 cities for the four-week period ending August 1 was 782 as compared with an expected weekly average of 717, an excess

		Week E	nding		4 Week	Weekly
	7/11	7/18	7 / 25	8/1	Total	Average
Observed	785	797	749	796	3,127	782
Expected	714	716	718	720	2,868	717
Excess	71	81	31	76	259	65

The table below which presents tour-week averages since the first of the year for each geographic division shows that in the past four-week period, all divisions reported an increase over the previous period, especially the Middle Atlantic, East North Central and South Atlantic. The reported increase may reflect delayed processing of death certificates or an actual increase in the number of infant deaths.
